MRI Brain WO/W Contrast

Patient:	KAREN CLAYBORNE	DOB:	Jan 11, 1966
-----------------	----------------------------	-------------	---------------------

REPORT

EXAMINATION: Brain MRI without and with IV contrast.

HISTORY: 59 years Female Lung cancer , Brain mets

TECHNIQUE: Multiplanar multisequence magnetic resonance imaging of the brain was performed without and with IV contrast.

CONTRAST: IV contrast was administered.

COMPARISON: CT head dated 5/30/2025.

FINDINGS: Previously demonstrated cystic and solid mass involving the cerebellar vermis has significantly decreased in size, now with solid enhancing component measuring 10 x 6 mm transaxially and 10 mm craniocaudally as well as a very small adjacent cystic component. The solid component previously measured over 3 cm. No additional abnormal intracranial contrast enhancement is detected. There is residual abnormal FLAIR signal along the superior aspect of the cerebellar vermis.

There is no evidence of diffusion restriction, additional intracranial mass lesion, intracranial hemorrhage, extra-axial fluid collections, or hydrocephalus. The major intracranial flow voids are normal.

The calvarium and skull base are normal. Orbital structures are within normal limits for age. The paranasal sinuses are well pneumatized without evidence of significant disease.

IMPRESSION:

1. Significant interval decrease in size of the previously demonstrated cystic and solid mass involving the cerebellar vermis, now with solid enhancing component measuring 10 x 6 x 10 mm as well as a very small adjacent cystic component. The solid component previously measured over 3 cm.
2. No additional abnormal intracranial contrast enhancement detected.
